

PROJECTILES

KEY WORDS & DEFINITIONS

- Projectile**
A particle moving in a vertical plane under the action of gravity.
- Angle of Projection**
The initial angle the projectile makes with the horizontal direction.
- Speed**
The magnitude of the velocity, or the resultant velocities.
- Range**
The horizontal distance that the particle travels.
- Time of Flight**
The time taken for the projectile to hit the ground, or other horizontal surface, after being projected.

HORIZONTAL & VERTICAL COMPONENTS OF INITIAL VELOCITY

If a particle is projected with an initial velocity u , at an angle α above the horizontal, α is called 'The angle of projection'.

The velocity can be resolved into components that act horizontally and vertically.

The horizontal component of the initial velocity
= $u \cos \alpha$

The vertical component of the initial velocity
= $u \sin \alpha$

WHAT DO I NEED TO KNOW

- The horizontal acceleration of a particle = 0
- The horizontal velocity of a particle is constant.
Therefore $s = vt$
- The vertical acceleration a of a particle = g (constant)
- To find the horizontal & vertical components of the initial velocity, resolve horizontally & vertically
- When a projectile reaches its maximum height, the vertical component of velocity = 0
- Acceleration due to gravity = 9.8 m/s^2
This does not depend on the mass of the object.
- The degree of accuracy in your answers must be consistent with the values given in the question.
I.e. if $g = 10 \text{ m/s}^2$ in the question, your answer should also be given to 1 sig. fig. Do not leave exact surd answers.
- Many projectile problems can be solved by first using the vertical motion to find the total time taken.

POSSIBLE EQUATIONS TO DERIVE

For a particle projected with initial velocity U at angle α above horizontal and moving freely under gravity:

- Time of flight = $\frac{2U \sin \alpha}{g}$
- Time to reach greatest height = $\frac{U \sin \alpha}{g}$
- Range on horizontal plane = $\frac{U^2 \sin 2\alpha}{g}$
- Equation of trajectory:

$$y = x \tan \alpha - \frac{gx^2}{2U^2} (1 + \tan^2 \alpha)$$

where y is the vertical height of particle and x is the horizontal distance from the point of projection.
